

# MiTM'ing Secured Communications in Automotive Apps

Month 10, 2017 |

Subtitle

---

**Ben Gardiner, Cloakware by Irdeto**

*Principal Security Engineer, GENIVI Alliance*

# About Me

- <https://www.linkedin.com/in/ben0l0gardiner/>
- 4 years experience in software security, 9+ years in embedded software design/development

# About Irdeto

Building a Secure Future.™

- Irdeto is a pioneer in digital platform and application security.
- ~50 years of security expertise.
- It's software security technology and cyber services:
  - Protect more than 5B devices & applications.
  - Protect against cyberattacks for some of the world's best known brands.

cloakware™ by irdeto  
*for automotive*

- Cloakware for Automotive by Irdeto helps automakers and tier-one suppliers protect their brand and save cost in the battle against cybercriminals by creating a secure, tamper-proof environment for vehicle software.

# Overview

- Man In The Middle
  - Background Information
    - SSL
    - Certificate Pinning
    - Integrity Verification
  - Protection Types
    - 1-6 levels
  - Attacks
    - Difficulties
      - In Field
      - At Home
- Tools
  - Proxy
    - Mitmproxy
    - Burp
    - OWASP ZAP
  - Hooking
    - Frida
    - JustTrustMe
- Examples
  - In Field Automotive Apps
    - Anonymous
- Appendix
  - Mitmproxy Setup

# What is MiTM?

- **Man in The Middle** attacks (MiTM / MITM)
- Intercepting and possibly modifying communications between two parties
  - without either party detecting the interception
  - assumed to mean bypassing encryption and authentication also -- when encrypted and/or authenticated communications are involved
- Where or not data is modified yields two *flavors* of the attack:
  - Siphon (no data modification)
  - Proxy
- Applicable to nearly all transport-layer and application-layer protocols in some form or another. In the following we will be discussing HTTP/HTTPS

# Agenda

- Examine the increasing levels of protection in HTTP/HTTPS communications
  - In mobile apps (focus on Android),
  - They are borne from mitigations against attacks

“Type”		Trust
Type 1		Trust anything (no SSL/TLS)
Type 2		Trust any valid certificate
Type 3		Trust any root-CA in OS “Trust Store”
Type 4		Trust only (pin) the pub key of certificate
Type 5		Trust only (pin) the pub key of cert. signer
Type 6		Pinning and <u>Integrity Verification</u>

# Type 1: Just HTTP (no S: SSL/TLS)

- No encryption, integrity or authentication in place
- A valid 'position' in the network is required
  - This depends on the network medium (see next slide)
- First; terminology for topologies

'Gateway' Position

'Sibling' Position

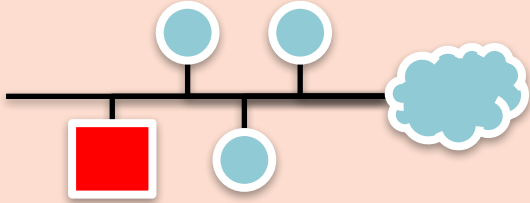

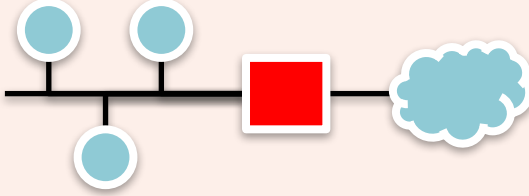

# Type 1 Defeat: Traffic Capture

- To view the unencrypted traffic attackers need only to receive the packets

Medium	Visibility from Sibling Position	Visibility from Gateway Position
Ethernet, Hub	Yes	Yes
Ethernet, Switch	Yes, with ARP-poisoning attack	Yes
Wi-fi	Yes	Yes, with Wi-fi Pineapple
Wi-fi +WEP	Yes	Yes, with Pineapple
Wi-fi +WPA2 PSK	Yes, with PSK known and captured WPA2 negotiation (e.g. de-auth attacks)	Yes, with Pineapple and PSK known
Wi-fi +WPA2 PSK Enterprise	No	Yes, with Pineapple and PSK known

# Discussion: Difficulty of Achieving Positions

		Difficulty in-field	... at-home
'Sibling' Position		Trivial (Ethernet, WEP) to Moderate (WPA2 PSK)	Trivial
'Gateway' Position		Easy (Wi-fi) to Unfeasible (WPA2 PSK Enterprise)	Trivial

# Type 1 Examples in Automotive Apps

- For all the applications surveyed, none. Which is good
- Minor exceptions: included some libraries pulled-in transitively by automotive apps
  - Remember to audit and/or test the behavior of your 3<sup>rd</sup> party components

## Discussion: Encryption without Authentication?

- It is possible to setup encrypted connections with a very-large pre-shared secret.
  - Not really feasible to deploy these systems at scale
- It is technically possible to setup negotiated encrypted channels at scale without authentication. c.f. TCPInc
  - These systems must negotiate their encryption keys during setup of the channel
  - Anyone eavesdropping on the channel setup (see Type 1 defeats) can discover the encryption keys
- Enter public-key crypto...
  - Dual-purpose the private keys used for identity also for setting up channel encryption immune to eavesdropping
- Reminder public key crypto can: enable a proof that a party has the private part of any public key

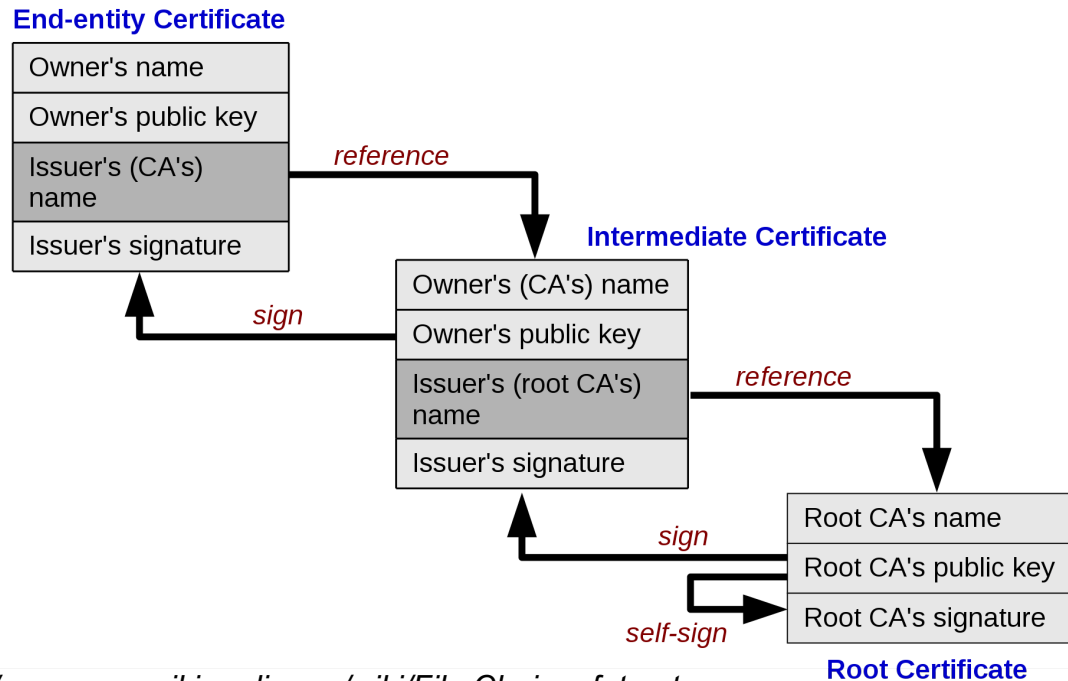

# Type 2: Trust 'any' Endpoint With Certificate

- Verify, in client HTTPS code, that the server has a valid certificate, any certificate
  - Validity here means signed by anything; including self-signed
  - Self-signed: signing the public key of the certificate with the private key of the same certificate

# Discussion: What are Certificates?

- Colloquially, for this presentation: the public keys and a signature of it against another certificate
  - In a chain

[https://commons.wikimedia.org/wiki/File:Chain\\_of\\_trust.svg](https://commons.wikimedia.org/wiki/File:Chain_of_trust.svg)

# Type 2 Defeat: Burp et. al.

- Proxy the HTTPS traffic; supply your own certificate to the clients
- Requires a 'gateway' position on the network (see Type 1)
  - Achievable in many in-field situations and also in all at-home situations
- Many tool options: Burp, OWASP ZAP, mitmproxy

Attack	Difficulty in-field	... at-home
Proxy Https Traffic	Moderate	Trivial

# Type 2 Example in Automotive Apps

- One example, non-critical use

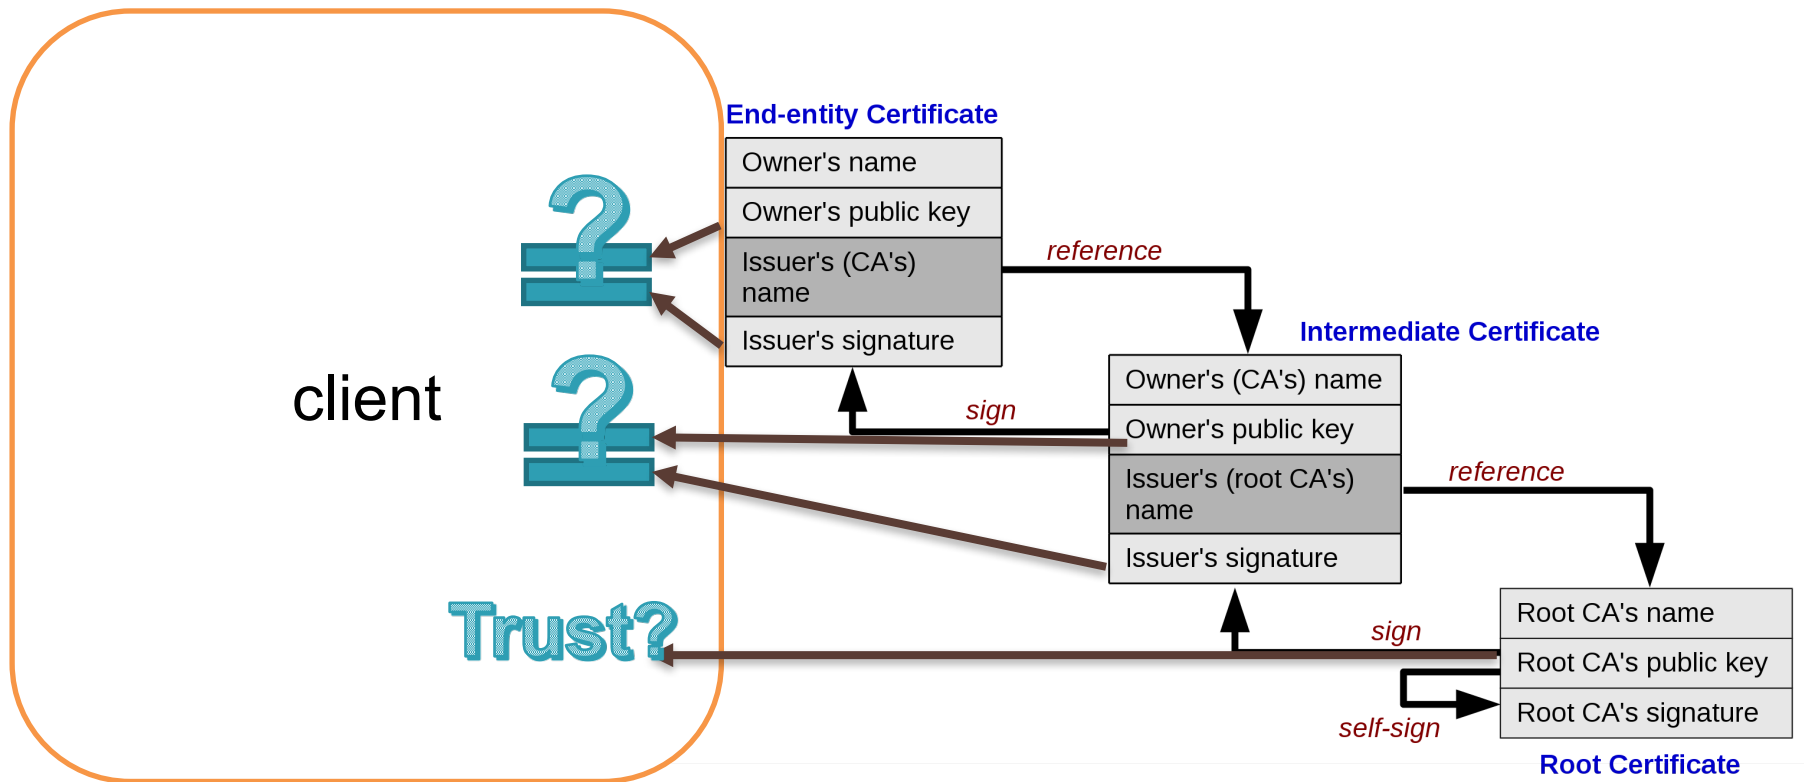

```
[0x0016d0c0]> VV @ sym.Lcom. [redacted] .method._init___V (nodes 1 edges 0 zoom 100%) BB-NORM mouse:canvas-y movements-speed:5
; 0x1bd20
new-instance v1, Lcom. [redacted] ; [ga]
invoke-direct {v1, v4}, Lcom. [redacted] .<init>(Lcom. [redacted] ;V ; 0x36d7;[gi]
invoke-static {v1}, Ljavax/net/ssl/HttpsURLConnection.setDefaultHostnameVerifier(Ljavax/net/ssl/HostnameVerifier;)V ; 0x5f11;[gj]
sget-object v1, Ljava/util/concurrent/TimeUnit;--SECONDS Ljava/util/concurrent/TimeUnit;
invoke-virtual {v0, v2, v3, v1}, Lcom/squareup/okhttp/OkHttpClient.setConnectTimeout(Ljava/util/concurrent/TimeUnit;)V ; 0x4a0f;[ak]
```

```
[0x0016d034]> VV @ sym.Lcom. [redacted] .1.method.verify_Ljava_lang_String_Ljavax_net_ssl_SSLSession__Z (nodes 1 edges 0 zoom 100%) BB-NORM mouse:canvas-y movem
```

```
[0x16d034] ;[ga]
;-- method.public.Lcom. [redacted] .1.Lcom. [redacted] .1.method.verify_Ljava_lang_String_Ljavax_net_ssl_SSLSession__Z:
(fcn) sym.Lcom. [redacted] .1.method.verify_Ljava_lang_String_Ljavax_net_ssl_SSLSession__Z:
sym.Lcom. [redacted] .1.method.verify_Ljava_lang_String_Ljavax_net_ssl_SSLSession__Z ();
; 0xffffffff
; -1
; -1
const/4 v0, 0x1; LiveOwnerManualSDK.java:52
return v0
```

- We also found many libraries with this pattern – appeared to be unused at runtime
  - Reminder: check what your third-party libraries are doing at runtime

# Discussion: Authentication via Chains of Trust

[https://commons.wikimedia.org/wiki/File:Chain\\_of\\_trust.svg](https://commons.wikimedia.org/wiki/File:Chain_of_trust.svg)

# Aside: HSTS

- Protects a website against these sorts of attacks, informing the user that this website is only to be accessed in HTTPS protocol
- Although certain sites are preloaded, it is possible to mitm the first connection to the site, and prevent the browser from receiving the HSTS flag
- This may also prevent cookie-downgrading attacks through a similar mechanism

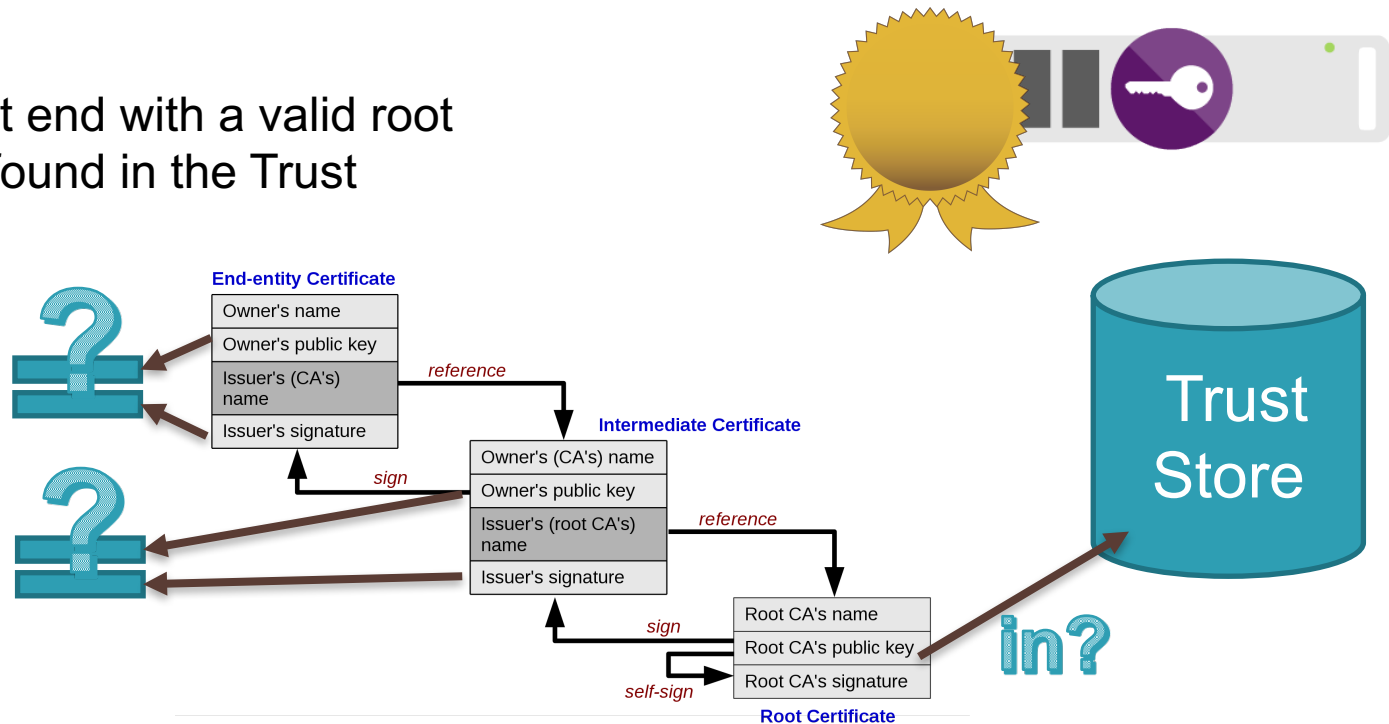

# Discussion: Authentication in Mobile OS and the Trust-Store.

- Android devices come preloaded with a list of trusted root Certificate Authorities that are inherent as trusted anchors. Anything signed by them will not throw security exceptions when the server is accessed
- iOS similarly comes with a preloaded list of trusted root CAs

# Type 3: Trust the Trust-Store

- All chains must end with a valid root CA certificate found in the Trust Store

[https://commons.wikimedia.org/wiki/File:Chain\\_of\\_trust.svg](https://commons.wikimedia.org/wiki/File:Chain_of_trust.svg)

# Type 3 Defeat: Add to the Trust-Store

- Custom user certs can be added,
- If root access is granted, can insert certs without user knowledge
- Improperly signed Certificates
- Private key leaks

Attack	Difficulty in-field	... at-home
Improperly signed Certificates	Difficult	Difficult
Private key leaks	Difficult	Difficult
Custom certificate installation	Moderate	Easy

# Type 3 Examples in Automotive Apps

- The vast majority of apps surveyed relied on the system Trust Store
- Default in Android and iOS; therefore many ways this type gets implemented

## Android trivial example from

```
URL url = new URL("https://wikipedia.org");
URLConnection urlConnection = url.openConnection();
InputStream in = urlConnection.getInputStream();
copyInputStreamToOutputStream(in, System.out);
```

# Deep-dive: HOWTO Setup mitmproxy for Android Testing

- Setting up environment
  - Longsword.sh Setup Scripts
  - Iptables modification
- Starting Proxy
  - Installing Certificate
  - Connection to Proxy
- Monitoring output

# Setting up Environment: Longsword init

```
deps () {
    printf "\nDownload the openvpn files to /etc/openvpn and add your secrets\s"
    set -x
    apt-get install hostapd isc-dhcp-server haveged
    systemctl enable hostapd
    systemctl enable haveged
    systemctl start haveged
    mkdir -p /etc/hostapd
    rm -f /etc/hostapd/hostapd.conf /etc/dhcp/dhcpd.conf /etc/default/isc-default-server
    ln -s "$PWD/hostapd.conf" /etc/hostapd/hostapd.conf
    ln -s "$PWD/dhcpd.conf" /etc/dhcp/dhcpd.conf
    ln -s "$PWD/isc-dhcp-server" /etc/default/isc-default-server
}

init () {
    WLAN="wlan0"
    [ -n "$1" ] && WLAN="$1"

    iptables-restore iptables.save
    sysctl -w net.ipv4.ip_forward=1 2>&1 >/dev/null

    #transparent proxying on $WLAN assuming the clients have custom gateway set, disable ICMP redirects
    echo 0 > /proc/sys/net/ipv4/conf/$WLAN/send_redirects

    systemctl restart hostapd

    ip link set "$WLAN" type wlan
    ifconfig "$WLAN" 192.168.25.1 netmask 255.255.255.0
    ip link set "$WLAN" up

    systemctl restart isc-dhcp-server
}
```

# Starting Mitmproxy

Most common starting arguments: `mitmproxy -T -host -anticache`

-T – transparent mode: with iptables config

-host : In the current setup of mitmproxy, it is in gateway form

-anticache: this allows a verbose look at server interactions

Other Helpful Commands:

-z : Convince servers to send uncompressed data

-replace PATTERN : Replacing server response that matches regex

# Details

[m:Auto]

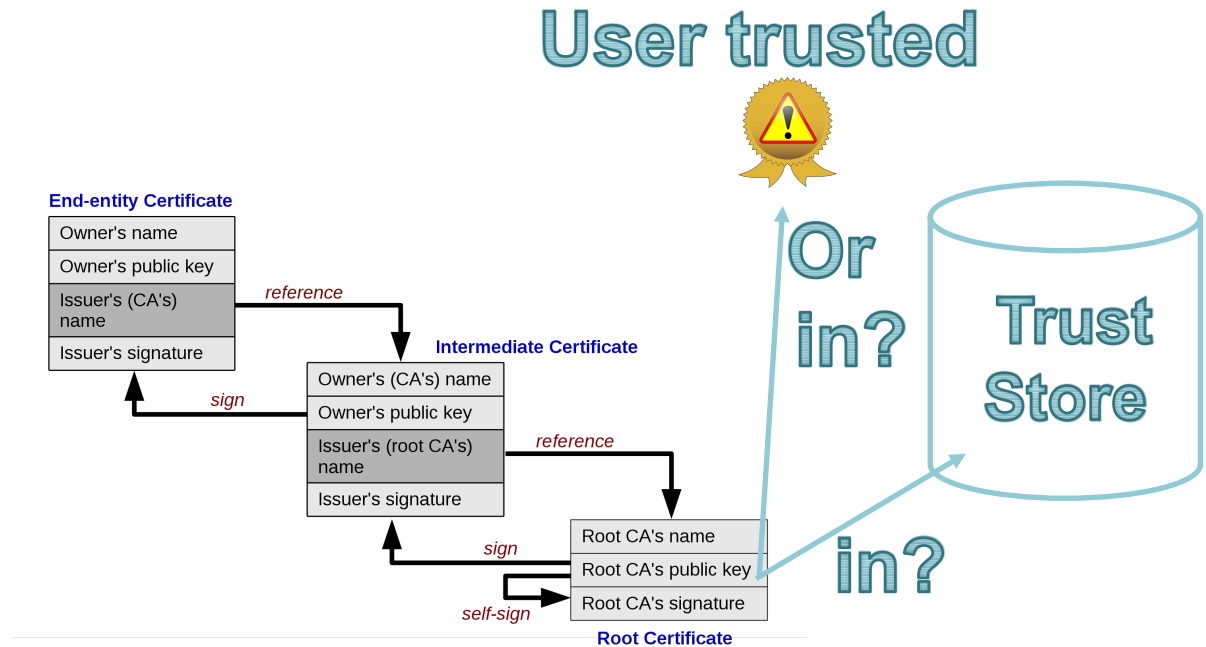

# The default Mitigation: Notification

Android will alert the user  
When a suspicious trust  
has been added

# Recap: how the Trust-Store was 'bypassed'

A User knowingly added the certificate to his trusted certs

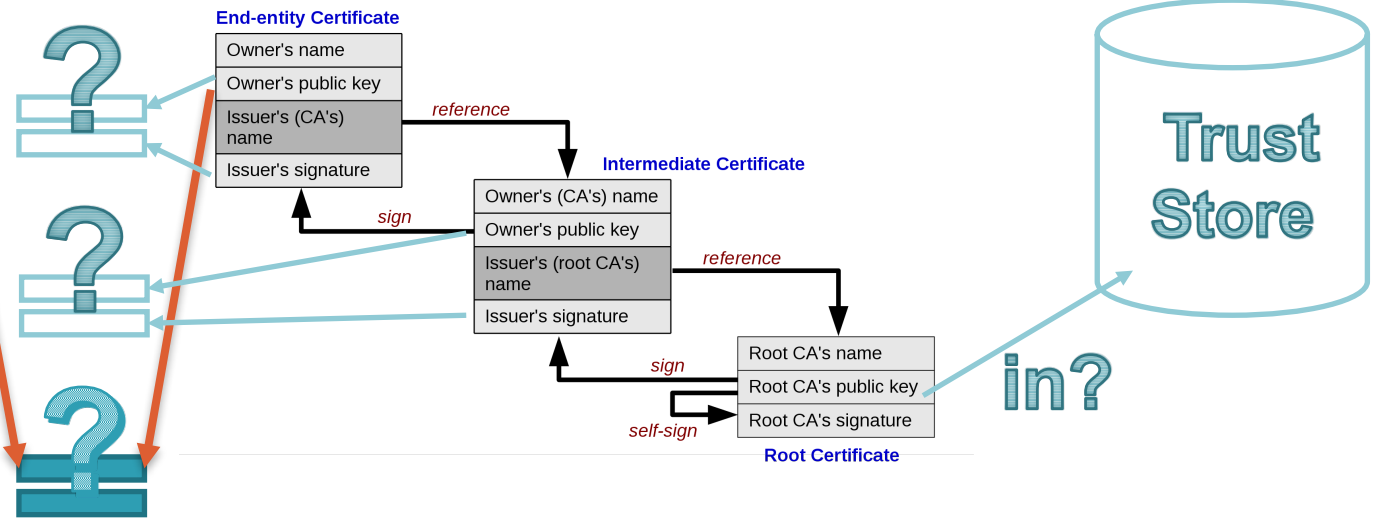

# Type 4: Trust the Public-Key of the endpoint.

- Verify server has an expected public key
  - variant: verify hash of public key

```

Legend

[https://commons.wikimedia.org/wiki/File:Chain\\_of\\_trust.svg](https://commons.wikimedia.org/wiki/File:Chain_of_trust.svg)

# Type 4 Defeats

- Collision with pub key
- Patch Software
- Disable SSL entirely with JustTrustMe ([github.com/Fuzion24/JustTrustMe](https://github.com/Fuzion24/JustTrustMe) )
- Patch certificate checks in Java using FRIDA (demo in Type 5)

| Attack               | Difficulty in-field | ... at-home |
|----------------------|---------------------|-------------|
| Public key Collision | Infeasible          | Infeasible  |
| Patch Software       | Infeasible          | Moderate.   |
| Disable SSL          | Infeasible          | Easy        |

# Type 4 Examples in Automotive Apps

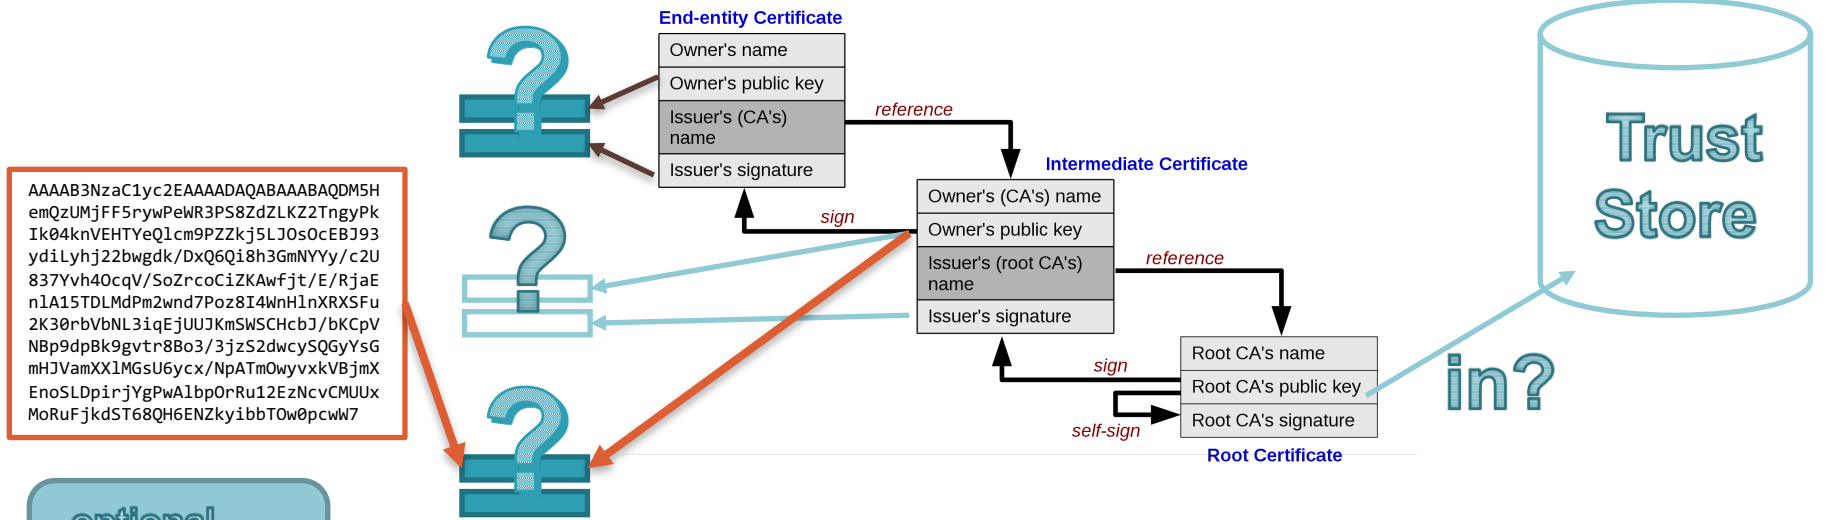

- For all the applications surveyed, none.
  - This method is inflexible to changes in the server certificates.

# Discussion: More on Pinning

- Type 4 (and Type 5, coming up) are "Certificate Pinning"
- This is the de-facto design to mitigate nearly all in-field attacks.
  - At-home attacks are still possible
- For many more details; consult [owasp.org/index.php/Certificate\\_and\\_Public\\_Key\\_Pinning](https://owasp.org/index.php/Certificate_and_Public_Key_Pinning)

# Type 5: Trust the Public-Key of a Signer of the Endpoint.

- Verify signer of the server's certificate has an expected public key
  - variant: verify hash of public key

```

# Type 5 Defeats: Same as Type 4

- All the type 4 defeats apply here too.

- Demo:

## FRIDA

- Frida, a javascript hooking engine.

- Installed through simple commands on rooted device

- `adb push frida-server /data/local/tmp`
- `adb shell "chmod 755 /data/local/tmp/frida-server"`
- `Adb shell "su -c chown root:root /data/local/tmp/frida-server"`
- `adb shell "/data/local/tmp/frida-server &"`

- Connect from host

- `frida -U -f <application> --codeshare pcipolloni/universal-android-ssl-pinning-bypass-with-Frida -no-pause`
- Additional api available in documentation page: ([www.frida.re/docs/home/](http://www.frida.re/docs/home/))

- Capture data before encrypted

# Type 5 Examples in Automotive Apps

- For all the applications surveyed, one.
  - But we can't show code sample from that one (even anonymized ones)

```
[0x00093698]> VV @ method.L[redacted].method.onEventAsync_Lorg_apache_http_method.build()Lorg/apache/http/impl/client/DefaultHttpClient; (nodes 10 edges 13 zoom 100%) BB-NORM m

    0x936f6 ;[ak]
```

# Type 6+: Integrity-Verification of Public Key

## Pinning Data

- Pin the certificate (or an intermediate certificate) AND verify that the application performing the check hasn't been tampered
  - Easy: verifying it hasn't been tampered on-disk (or NAND or whatever)
  - Harder: verifying it hasn't been tampered in-memory
  - Hardest: doing either of those in a way that an attacker at-home can't easily disable

# Type 6 Defeats

| Bypass certificate pinning AND                                      | Difficulty in-field | ... at-home                                                                      |
|---------------------------------------------------------------------|---------------------|----------------------------------------------------------------------------------|
| Bypass simple on-disk IV                                            | Infeasible          | Easy (e.g. repackage APK) to<br>Difficult (e.g. patch-out IV, use iOS jailbreak) |
| Bypass simple in-memory IV                                          | "                   | Difficult (patch-out IV)                                                         |
| Bypass mutually-reinforcing protections around on-disk/in-memory IV | "                   | "Very" Difficult (reverse-engineer & patch-out all)                              |
| Bypass renewable mutually-...                                       | "                   | Infeasible (attacker efforts restarted repeatedly)                               |

# Type 6 Examples in Automotive Apps

- None (yet).
  - This is a common design for media players and mobile banking apps, but the automotive apps haven't reached this level of sophistication yet.

# Review

- Type system progression
  - Protections
  - Defeats
  - Automotive Examples
- Tools
  - MitmProxy
  - FRIDA
- What Type level is correct?

# Thank you!

# Appendix 1: Mitmproxy setup

- Detailed documents listed at <http://docs.mitmproxy.org/en/latest/install.html>
  - It might be worth using a specific device for the setup.
- Installation Options
  - Binary Download options: [releases page](#)
  - Package manager options:
    - Homebrew on OSX
      - `brew install mitmproxy`
    - Pacman on Arch Linux
      - `sudo pacman -S mitmproxy`
  - Source:
    - Python
      - `pip3 install mitmproxy`

# Appendix 1: Mitmproxy Setup Certs

- mitmproxy generates its own certificate into the `~/.mitmproxy/mitmproxy-ca.pem`
- If a custom certificate is needed, this can be specified with the `-client-certs` option.
  - Requirements:
    - installation of new root certificates onto android device
    - Creation of self signed root CA through openssl
